

Can the muscle proteome classify cancer-survivor status and training response?

Three feature spaces differing in how far their definition sits from these data. Exploratory: 25 baseline samples, 12 paired subjects; permutation nulls, not confirmatory claims.

A

Cross-validated classification

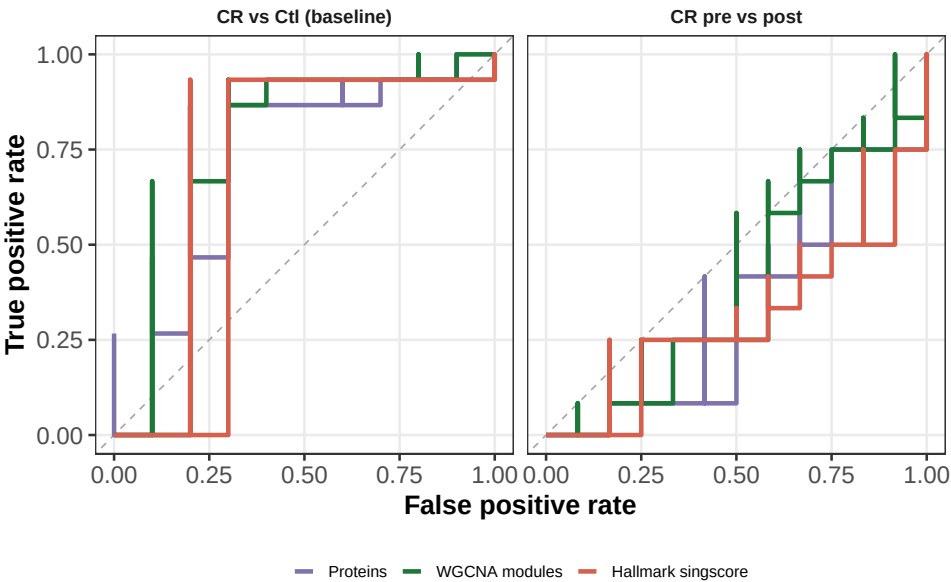

bars = AUC, whiskers = DeLong CI, p = permutation null

B

ROC by feature space

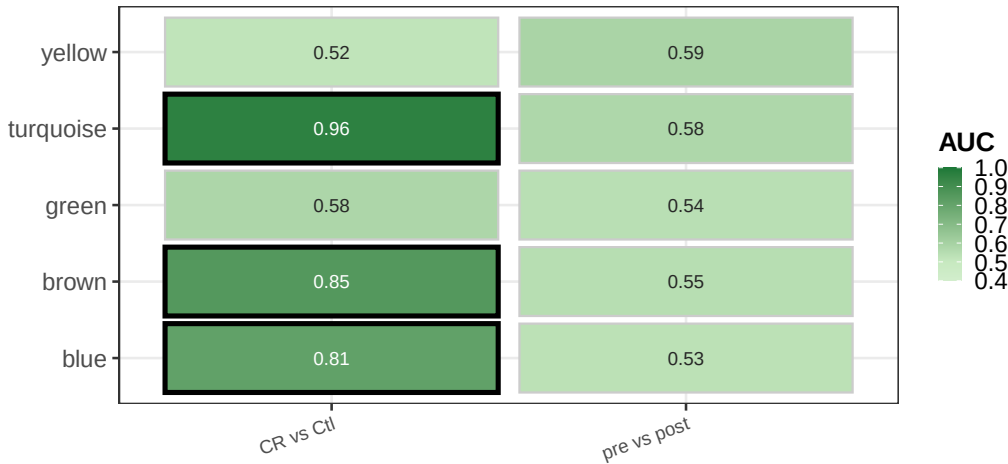

out-of-fold predictions

C

Single-module association

in-sample AUC; box = module survives every leave-one-out refit

D

Does module membership explain reversal?

297 disease-signature proteins; grey = unassigned
10-fold AUC 0.60 [0.53-0.67], perm $p=0.015$ | chi-sq $p=0.23$
